Theorem

Discrete
Logarithms

- prime numbers only have divisors of 1 and self
- to factor a number n is to write it as a product of other numbers: $n=a \times b \times c$
- note that factoring a number is **relatively hard compared to multiplying the factors together** to generate the number
- the prime factorisation of a number n is when its written as a product of primes eg. $91=7 \times 13$; $3600 = 2^4 \times 3^2 \times 5^2$

$$a = \prod_{p \in P} p^{a_p}$$

- **Relatively Prime Numbers:** two numbers **a**, **b** are relatively prime if they have no common divisors **except 1**

Remainder
Theorem

Discrete
Logarithms

- when doing arithmetic **modulo n**
- **complete set of residues** is: $0..n-1$
- **reduced set of residues** is those numbers (residues) which are **relatively prime to n**
- eg for $n=10$,
complete set of residues is $0,1,2,3,4,5,6,7,8,9$
reduced set of residues is $1,3,7,9$
- **number of elements in reduced set of residues** is called the **Euler Totient Function $\phi(n)$**

- a generalisation of Fermat's Theorem

$$a^{\phi(n)} \bmod N = 1$$

- where **$\gcd(a, N) = 1$**
- eg. $a=3$; $n=10$; $\phi(10)=4$;
- hence $3^4 = 81 = 1 \bmod 10$
- $a=2$; $n=11$; $\phi(11)=10$;
- hence $2^{10} = 1024 = 1 \bmod 11$

Discrete
Logarithms

- often need to find large prime numbers
- traditionally sieve using trial division
- ie. divide by all numbers (primes) in turn less than the square root of the number
- only works for small numbers
- alternatively can use statistical primality tests based on properties of primes
- for which all primes numbers satisfy property
- but some composite numbers, called pseudo-primes, also satisfy the property

Is 561 prime ?

- 1 Find $561 - 1 = 2^k \cdot m$
- 2 Choose a , $1 < a < n - 1$
- 3 Compute $b_0 = a^m \bmod n$
- 4 if $b_0 = +1 \implies n$ is a composite number
 else if $b_0 = -1 \implies n$ may be a prime number
- 5 Compute $b_i = b_{i-1}^2$, check for composite or prime
- 6 Repeat step number 5

- if Miller-Rabin returns "composite" the number is definitely not prime
- otherwise is a prime or a pseudo-prime
- chance it detects a pseudo-prime is $< 1/4$
- hence if repeat test with different random a then chance n is prime after t tests is:
- $\Pr(n \text{ prime after } t \text{ tests}) = 1 - 4^{-t}$
eg. for $t=10$ this probability is > 0.99999

Chinese Remainder Theorem: If m_1, m_2, \dots, m_k are pairwise relatively prime positive integers, and if a_1, a_2, \dots, a_k are any integers, then the simultaneous congruences

$$x \equiv a_1 \pmod{m_1}, \quad x \equiv a_2 \pmod{m_2}, \quad \dots, \quad x \equiv a_k \pmod{m_k}$$

have a solution, and the solution is unique modulo m , where

$$m = m_1 m_2 \dots m_k.$$

To compute $X \pmod{M}$

- first compute all $a_i = A \pmod{m_i}$ separately
- determine constants c_i ,
where $M_i = M/m_i$
- then combine results to get answer using:

$$X \equiv (\sum_{i=1}^k a_i c_i) \pmod{M}$$

$$c_i = M_i \times (M_i^{-1} \pmod{m_i}) \text{ for } 1 \leq i \leq k$$

Using the Chinese Remainder theorem:

$$a_1 = 2 ; a_2 = 3 ; a_3 = 2 ;$$

$$m_1 = 3 ; m_2 = 5 ; m_3 = 7 ;$$

- $M = m_1 \times m_2 \times m_3 = 3 \times 5 \times 7 = 105$

- $M_1 = M/m_1 = 105/3 = 35$

- 2 is an inverse of $M_1 = 35 \pmod{3}$
(since $35 \times 2 \equiv 1 \pmod{3}$)

- $M_1 \cdot M_1^{-1} \equiv 1 \pmod{m_1} \implies 35 \cdot M_1^{-1} \equiv 1 \pmod{3}$

- $\gcd(35,3); \gcd(3,2); \gcd(2,1); \gcd(1,0) = 1$

- $35 = 11 \times 3 + 2 \implies 2 = 35 - 11 \times 3$

- $3 = 1 \times 2 + 1 \implies 1 = 3 - 1 \times 2$

- $1 = 3 - 1 \times 2$
 $= 3 - (35 - 11 \times 3) = -1 \times 35 + 12 \times 3$

- $1 = -1 \times 35 + 12 \times 3; -1 \times 35 \equiv 1 \pmod{3}$
 $\implies 2 \times 35 \equiv 1 \pmod{3}; \mathbf{2}$ is inverse of $\mathbf{35 \pmod{3}}$

Chinese
Remainder
Theorem

Discrete
Logarithms

Using the Chinese Remainder theorem:

- $M_2 = M/m_2 = 105/5 = 21$
 - 1 is an inverse of $M_2 = 21 \pmod{5}$ (since $21 \times 1 \equiv 1 \pmod{5}$)
- $M_3 = M/m_3 = 105/7 = 15$
 - 1 is an inverse of $M_3 = 15 \pmod{7}$ (since $15 \times 1 \equiv 1 \pmod{7}$)
- So , $X \equiv 2 \times 2 \times 35 + 3 \times 1 \times 21 + 2 \times 1 \times 15 = 233 \equiv 23 \pmod{105}$
- So answer: $X \equiv 23 \pmod{105}$

Discrete
Logarithms

- The inverse problem to exponentiation is to find the **discrete logarithm of a number modulo p**
- That is to find **i** such that **$b = a^i \pmod{p}$**
- This is written as **$i = \text{dlog}_a b \pmod{p}$**
- If **a** is a primitive root then it always exists, otherwise it may not,
eg.
- The discrete logarithm does not always exist, for instance there is no solution to
 $2^x \equiv 3 \pmod{7}$.
- There is no simple condition to determine if the discrete logarithm exists.
- Whilst exponentiation is relatively easy, **finding discrete logarithms is generally a hard problem**

Theorem

Discrete
Logarithms

For example, consider Z_{23}

To compute 3^4 in this group, we first compute $3^4=81$, and then we divide 81 by 23, obtaining a remainder of 12. Thus $3^4=12$ in the group Z_{23}^*

Discrete logarithm is just the inverse operation. For example, take the equation $3^k \equiv 12 \pmod{23}$ for k . As shown above $k=4$ is a solution, but it is not the only solution. Since $3^{22} \equiv 1 \pmod{23}$, it also follows that if n is an integer then $3^{4+22n} \equiv 12 \times 1^n \equiv 12 \pmod{23}$. Hence the equation has infinitely many solutions of the form $4+22n$.
