Module M44: C++ Standard Library (STL): Part 2

Partha Pratim Das

Department of Computer Science and Engineering Indian Institute of Technology, Kharagpur

ppd@cse.iitkgp.ac.in

All url's in this module have been accessed in September, 2021 and found to be functional

Programming in Modern C++ Partha Pratim Das M44.1

Module Recap

Objectives & Outlines

• Overview of Standard Library components of C++

• Learnt fundamentals of generic programming

Programming in Modern C++ Partha Pratim Das M44.2

Module Objectives

Objectives & Outlines

- To understand Standard Template Library (STL)
- To understand common containers (data structure) and their use

STL: Standard Template Library

Module M4

Partha Pratii Das

Objectives Outlines

The STL Policy

Common Components vector list map set

Andula Summar

- Part of the ISO C++ Standard Library
- Has four components:
 - o containers
 - o iterators
 - algorithms
 - o functions
- Mostly non-numerical
 - Only 4 standard algorithms specifically do computation
 - ▷ accumulate, inner_product, partial_sum, adjacent_difference
- Handles textual data as well as numeric data
 - o For example, string
- Deals with organization of code and data
 - o Built-in types, user-defined types, and data structures
- Optimizing disk access is among its original uses
 - o Performance is always a key concern

The STL

Module M4

Partha Pratii Das

Objectives Outlines

The STL Policy

Common Components vector list map set

Module Summa

• Designed by Alex Stepanov

- General aim: *Most general, most efficient, most flexible* representation of concepts (ideas, algorithms)
 - o Represent separate concepts separately in code
 - Combine concepts freely wherever meaningful
- General aim to make programming like math
 - o or even Good programming is math
 - works for integers, for floating-point numbers, for polynomials, for . . .

The STI

The STI

• An ISO C++ standard framework of about 10 containers and about 60 algorithms connected by iterators

- Other organizations provide more containers and algorithms in the style of the STL
 - Doost.org: Boost provides free peer-reviewed portable C++ source libraries. It has several containers include a number of non-standard containers (like stable_vector. flat_(multi)map/set associative containers, slist. static_vector. and small_vector
 - ▶ MSVC STL: Microsoft VC++ Standard Library has been released as open source: Open Sourcing MSVC's STL, 2019
 - ▶ Dinkumware Standard C++ Library
 - ⊳ SGI
- The best known and most widely used example of generic programming

The STL

Policy Parameteriza

Common Component vector

list map

Module Summ

Separation of Concerns

- Algorithms manipulate data, but do not know about Containers
- Containers store data, but do not know about Algorithms
- Algorithms and Containers interact through Iterators
- Each Container has its own iterator types

Basic Model: Iterators: Recap (Module 43)

Module M44

Partha Pratir Das

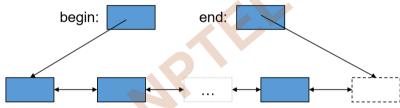

Objectives Outlines

The STL Policy

Common Components vector list map

Module Summa

- A pair of iterators defines a sequence
 - The *beginning* (points to the *first element* if any)
 - The end (points to the one-beyond-the-last element)

- An iterator is a type that supports the *iterator operations*
 - ++ Go to next element
 - * Get value
 - Does this iterator point to the same element as that iterator?
- Some iterators support more operations (for example, --, +, and [])

Basic Model: Algorithms + Iterators: Recap (Module 43)

Double Double

Objectives Outlines

The STL

Common Components vector

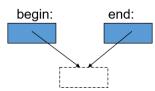

map set

Module Summa

- An iterator points to (refers to, denotes) an element of a sequence
- The end of the sequence is *one past the last element*
 - o not the last element
 - That is necessary to elegantly represent an empty sequence
 - o One-past-the-last-element is not an element
 - ▶ You can compare an iterator pointing to it
 - ➤ You cannot dereference it (read its value)
- Returning the end of the sequence is the standard idiom for not found or unsuccessful

some iterator: the end: 0 1 2 3

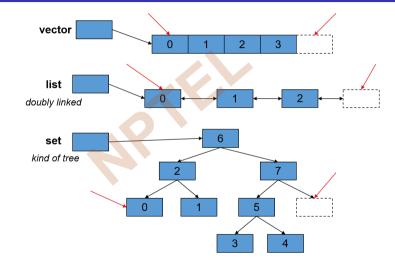

An empty sequence:

Outlines
The STL

Policy Parameterization

Common
Components
vector
list
map
set

- \bullet When we have a useful algorithm, we may want to $\emph{parameterize}$ it by a \emph{policy}
 - o For example, we need to parameterize sort by the comparison criteria

```
struct Record {
    string name; // standard string for ease of use
    char addr[24]: // old C-style string to match database layout
vector<Record> vr:
sort(vr.begin(), vr.end(), Cmp_by_name()); // sort by name
sort(vr.begin(), vr.end(), Cmp_by_addr()); // sort by addr
// Different comparisons for Rec objects
struct Cmp_by_name {
    bool operator()(const Record& a, const Record& b) const
        { return a.name < b.name: } // look at the name field of Record
};
struct
       Cmp_bv_addr {
    bool operator()(const Record& a, const Record& b) const
        { return 0 < strncmp(a.addr, b.addr, 24); } // look at the addr field of Record
};
// Note how the comparison function objects are used to hide ugly and error-prone code
Programming in Modern C++
                                                      Partha Pratim Das
```

Policy Parameterization

Policy

Parameterization

Common Components vector list map set

set

• Lambda or closure object may be used to parameterize a policy

Programming in Modern C++ Partha Pratim Das M44.16

Policy Parameterization

Module M4

Partha Pratir Das

Objectives Outlines

Policy Parameterization

Common Components vector list map set

Module Summa

• Use a *named object* as argument

- If you want to do something complicated
- o If you feel the need for a comment
- If you want to do the same in several places
- Use a lambda expression as argument [C++11]
 - If what you want is short and obvious
- Choose based on *clarity of code*
 - o There are no performance differences between function objects and lambdas
 - o Function objects (and lambdas) tend to be faster than function arguments

```

Objectives Outlines

The STL Policy Parameteriz

Common
Components
vector
list
map
set

Module Summar

- Know both ways (iterator and subscript)
 - The subscript style is used in essentially every language
 - The iterator style is used in C (pointers only) and C++
 - The iterator style is used for standard library algorithms
 - The subscript style does not work for lists (in C++ and in most languages)
- Use either way for vectors
 - There are no fundamental advantages of one style over the other
 - But the iterator style works for all sequences
 - Prefer size_type over plain int

Ways of traversing a vector

vector vs. list

Nodule M4

Partha Pratir Das

Objectives Outlines

Policy

Policy Parameteriza

Common Components vector list map set

Module Summa

- By default, use a vector
 - We need a reason not to
 - We can grow a vector (for example, using push_back())
 - We can insert() and erase() in a vector
 - Vector elements are compactly stored and contiguous
 - For small vectors of small elements all operations are fast
- If we do not want elements to move, use a list
 - We can grow a list (for example, using push_back() and push_front())
 - We can insert() and erase() in a list
 - List elements are separately allocated
- Note that there are more containers like
 - o map
 - o unordered_map [C++11]

map: An associative array

- For a vector, we subscript using an integer
- For a map, we can define the subscript to be (just about) any type
- After vector, map is the most useful standard library container
 - Maps (and/or hash tables) are the backbone of scripting languages
- A map is really an ordered balanced binary tree, by default ordered by < (less than)

```
// note the similarity to vector and list
template < class Key, class Value > class map
    using value_type = pair<Key, Value>; // a map deals in (Key, Value) pairs
    using iterator = ???; // Some implementation defined type - probably a pointer to a tree node
   using const iterator = ???:
    iterator begin(); // points to first element
    iterator end(): // points to one beyond the last element
    Value& operator[](const Key&); // get Value for Key; creates pair if necessary, using Value()
    iterator find(const Kev& k): // is there an entry for k?
    pair<iterator, bool> insert(const value_type&); // insert new (Key, Value) pair
                                                    // the bool is false if insert failed
    void erase(iterator p):
                                  // remove element pointed to by p

Common Components vector list map

Module Summa

- sets are containers that store *unique elements* following a specific order
- In a set, the value of an element also identifies it (the value is itself the key, of type T), and each value must be unique
- Internally, the elements in a set are always sorted following a specific strict weak ordering criterion indicated by its internal comparison object (of type Compare)
- set containers are generally slower than unordered_set containers
- Sets are typically implemented as binary search trees
